\$ACM deployment for the 99¢ "Bring Back the Castle" program

August 2026 · scope: this program only · all inputs read live and stated below

THE 99¢ IS A DONATION TO BRING BACK ALADDIN'S CASTLE — not an investment in \$ACM, not solicited as one, no expectation of profit. The token grant is a membership credential with no cash value inside the system. Custody, placement and revocation are disclosed in the ULA.

01

Live inputs — every figure below derives from these

Market	Value	Program	Value
SOL	\$73.00	App price	\$0.99
\$ACM	\$0.00022720	Apple commission	15% (Small Business)
Pool base (pumpswap)	91,578,851 ACM	Grant per download	1 ACM
Pool quote	285.38 SOL = \$20,833	Wallet held	11,767,037 ACM
Total liquidity	\$41,639	released as pool	10,000,000
\$ACM total supply	999,957,146	R&D reserve	1,767,037

A prior draft used \$200/SOL and a 42.9M-token pool. Both were wrong. SOL is \$73, which cuts account rent by 63%, and the pool holds more than twice the tokens assumed. Every number here is rebuilt on the live figures above.

02

Sources

Source	Amount	Character
\$ACM already owned	11,767,037 ACM	zero cost basis to the program
— released as funding pool	10,000,000	grants, one token per download
— held as R&D reserve	1,767,037	never granted
App revenue , gross per download	\$0.9900	the only recurring cash source
Net contribution per download	\$0.6916	70% of the 99¢, after every cost below

03

Uses

RECURRING · per download

Use	Amount	% of 99¢
Apple commission, 15%	\$0.1485	15%
Solana account rent	\$0.1489	15%
Transfer fee	\$0.0010	0%
\$ACM grant, from free pool	\$0.0000	0%
Retained	\$0.6916	70%

Rent is 0.00204 SOL, non-recoverable in practice — a user who changes phones leaves a wallet we cannot reclaim. It is the only cost that scales with users and does not come back.

ONE-TIME · token inventory

Tokens bought	Cost	Avg \$/token
10,000,000	\$2,554	\$0.000255
20,000,000	\$5,821	\$0.000291
40,000,000	\$16,156	\$0.000404
65,000,000	\$50,948	\$0.000784
85,000,000	\$269,163	\$0.003167
91,578,851	pool empty	→ ∞

Priced on the constant-product integral, so slippage is included — the average paid rises from 1.1× spot at 10M tokens to 13.9× at 85M.

04

The finding

99¢ never breaks on cost. It breaks on supply.

Even at one hundred million downloads the token costs **\$0.0119** per download against **\$0.6916** of contribution — a 58× margin. The binding constraint is that the pool physically contains **91,578,851 ACM** and the 91,578,852nd cannot be bought at any price.

Downloads	Tokens to buy	Cost per download	Against \$0.6916 contribution
10,000,000	0	\$0.0000	free — covered by the released pool
25,000,000	15,000,000	\$0.0002	4,237× margin
50,000,000	40,000,000	\$0.0003	2,140× margin
75,000,000	65,000,000	\$0.0007	1,018× margin
100,000,000	90,000,000	\$0.0119	58× margin
CEILING — pool exhausted		101,578,851 downloads	

What to buy, and the one decision that sets the ceiling

05

Deployment options

Buy now	Cost	Total inventory	Revenue those downloads generate	Cost as % of revenue
nothing	\$0	10,000,000	\$6,915,800	0.000%
10,000,000	\$2,554	20,000,000	\$13,831,600	0.018%
20,000,000	\$5,821	30,000,000	\$20,747,400	0.028%
40,000,000	\$16,156	50,000,000	\$34,579,000	0.047%
65,000,000	\$50,948	75,000,000	\$51,868,500	0.098%

\$16,156 buys inventory for fifty million downloads — five hundredths of one percent of the revenue those downloads produce. There is no version of this where the token is the expensive part.

06

The decision that actually matters

\$ACM carries **six decimals**. The grant does not have to be a whole token, and eligibility is a threshold test — the system asks whether a holder has a credential, not how large it is. That makes grant size a free parameter, and it is the only thing that moves the ceiling.

Grant	Free pool alone covers	Pool + entire market	Inventory to buy	vs Instagram 762M
1 ACM	10,000,000	101,578,851	\$16,156 for 50M dl	falls short
0.1 ACM	100,000,000	1,015,788,510	none needed	covers
0.01 ACM	1,000,000,000	10,157,885,100	none needed	covers 1.3×

At 0.01 ACM per download the released ten-million pool alone covers a billion downloads and no purchase is ever required. At 1 ACM it covers ten million and the ceiling is 101.6 million however much you spend.

Two consequences to weigh, not resolved here. A fractional grant is harder to describe than "you own one \$ACM," and it removes even the small float-reduction effect a whole-token grant produces. Both are messaging and tokenomics questions, not engineering ones. If the whole-token grant is kept for narrative reasons, the ceiling of 101.6M downloads is a deliberate, priced choice — not an oversight.

07

Recommended deployment

When	Action	Capital	Rationale
NOW	Decide grant size: 1 vs 0.01 ACM	\$0	sets the ceiling at 101.6M or 10.2 billion downloads; everything else follows from it
NOW	If 1 ACM: buy 40,000,000	\$16,156	secures 50M downloads; the average price paid triples again by 85M tokens
NOW	If 0.01 ACM: buy nothing	\$0	the released pool already covers a billion downloads
PRE	Mint the wallet on first engagement, not on download	—	rent is 15% of gross and the only recoverable line that scales
ONGOING	Do not redeploy profit into the pool	—	buying beyond inventory need buys price, not tokens, and raises what you pay next

\$16,156

Total \$ACM capital required to launch and support fifty million downloads at one token each — against **\$34.6M** of contribution those downloads generate. If the grant is fractional instead, the figure is **\$0**.

The program is cash-positive from the first download. There are no fixed costs in this model — no minimum spend, no threshold to clear, no volume required before it works. The 99c covers its own token, its own rent and Apple's commission with 70c left over, and it does so on download one exactly as it does on download ten million.
